

Class Engagement Report

Session: classroom_session | Duration: 36m 27s | Generated: 30 July 2026, 22:02

Average engagement	77%
Lowest point	0% at 0m 09s
Attention drops detected	14
Phone use	visible for 1% of session (peak 3 at once)

Engagement across the session

The green line shows class engagement smoothed over time; the dashed line marks the session average. Shaded areas indicate periods where engagement fell substantially below that average for a sustained interval.

Moments that warrant attention

Period	Lowest engagement
0m 51s - 1m 12s	0%
9m 17s - 9m 41s	0%
11m 28s - 11m 41s	0%
13m 24s - 13m 39s	0%
17m 22s - 17m 42s	0%
21m 21s - 21m 32s	0%
25m 22s - 25m 43s	0%
28m 45s - 28m 54s	0%
29m 14s - 29m 19s	0%
29m 40s - 30m 56s	0%
33m 10s - 33m 16s	0%

33m 51s - 34m 23s	0%
34m 55s - 35m 05s	0%
36m 03s - 36m 21s	0%

Recommended actions

The following suggestions are derived from the patterns in this session's data. They are prompts for your own judgement rather than instructions: you know what was being taught at each of these moments, and that context should always take precedence over the measurement.

- **Review the material taught between 0m 51s and 1m 12s.** Engagement fell to 0% during this period, well below the session average of 77%. Consider whether the concept introduced here was conceptually difficult, delivered too quickly, or presented without a worked example, and plan to revisit it early in the next session.
- **Consider introducing a short break or an activity change in the final third of the session.** Attention declined most in the later part of the class, which is consistent with the natural attention decay observed in extended teaching sessions. A two-minute pause, a question to the room, or a switch to paired discussion typically restores attention more effectively than continuing at the same pace.
- **Review the overall pacing of the session.** 14 separate attention drops were detected, which suggests the difficulty may lie in the rhythm of delivery rather than in any single topic. Alternating between exposition and short interactive segments every 10 to 15 minutes is a well-established remedy.
- **Engagement peaked around 1m 58s, reaching 100%.** Identifying what was happening at this point is as valuable as examining the low points: whatever format or material held attention here is worth using more often.

How to use this report

This report is intended as a private aid to your own reflection on the session. It is not an assessment of your teaching, and it is not a record of individual students: every figure it contains describes the class as a whole, and the source recording is deleted once the analysis is complete.

The most useful way to read it is to work backwards from the flagged moments. Take each timestamp in the table above and recall what was happening at that point in the class - which concept you were introducing, which format you were using, how long you had been speaking without interruption. The system can identify *when* attention fell, but only you can supply the *why*, and it is the combination of the two that turns a measurement into a teaching decision.

Three practical uses follow from this. In the short term, the flagged periods indicate material that may benefit from being revisited at the start of the next session. In the medium term, comparing reports across several sessions will show whether a change you have made - a different pacing, an added activity, an earlier break - has had a measurable effect. And in preparing future iterations of the same material, the periods of highest engagement are as informative as the lowest, since they indicate formats worth repeating deliberately.

A single report should be treated as one observation rather than a conclusion. Engagement varies with the time of day, the point in the term, the assessment calendar, and factors entirely outside the classroom. Patterns that persist across several sessions are meaningful; a single unusual session usually is not.

Interpreting the measurement

This system measures **behavioural** engagement: the observable signals of attention such as head orientation, posture, stillness and visible device use. It does not measure understanding, interest, or any internal state, and it should not be read as doing so. A student may be attentive while appearing still, or thinking deeply while looking away; conversely, apparent attention does not guarantee comprehension.

Detection accuracy also varies with conditions. Students seated furthest from the camera, partially occluded, or working with their heads down are measured less reliably than those clearly in view, and fairness analysis has shown that accuracy is not perfectly uniform across individuals. This is the reason results are reported only at class level: the measurement is sufficiently reliable to describe the pattern of a room over time, and deliberately not used to characterise any individual student.
